

Use of a **CeraPlus™ Skin Barrier** with Remois Technology*

Case Study 12

Abstract

There is a high incidence of peristomal skin complications, with more than half of all people living with an ostomy experiencing a peristomal skin issue at some point in their lifetime¹. The types of complications, the reasons for them, and the solutions used to treat them can vary widely. For clinicians, managing these peristomal skin complications takes time and effort. For patients, sore peristomal skin can have a huge impact on their quality of life. Peristomal skin complications are the most common post-operative complication following creation of a stoma². One such story will be shared in this case study.

Aim

To visibly improve and maintain peristomal skin integrity by finding a suitable skin barrier formulation for the patient, and ensuring a proper skin barrier fit around the stoma.

Photo 2 Intervention and product application.

Patient Overview

The patient is a middle aged male with a diagnosis of colon cancer (sigmoid colon). The rectal mass involved his bladder and prostate resulting in both an ileostomy and a urostomy. He was being treated with both chemo (oral and IV) and radiation therapy. He was admitted to the hospital for carboplatin induced mucositis. The WOC nurse was consulted because his ileostomy was leaking during this hospitalization. The pouching system around the urostomy was providing a good seal with a four day wear time. This case study will focus on management of the ileostomy.

Patient was very positive and understood that this was a temporary complication. He believed that the WOC nurse would be able to help him and his family was supportive and willing to assist him.

Problem

The patient was using a two-piece extended wear cut-to-fit convex skin barrier with a barrier ring to manage his ileostomy. He was getting a 4 day wear time prior to skin break down. The top layer of skin had sloughed off and was now moist and weeping (Photo 1). His wear time decreased to a few hours and he was having a lot of pain. The tape border of the skin barrier on the urostomy pouching system was cut away to keep it off his denuded skin and help minimize the pain.

Interventions

A strip of skin barrier was applied to the skin between the two stomas to prevent leakage from the ileostomy from breaking the seal around the urostomy. A barrier ring was added to the back of a two-piece **CeraPlus** cut-to-fit convex skin barrier (Photo 2) and applied around the ileostomy. Once in place, a hydrocolloid was used to cover the tape border of both skin barriers and the strip of skin barrier between the two stomas. In addition, an abdominal binder was placed to prevent staff from removing his pouching systems.

Case Study 12

Outcomes

Upon assessment four days later, the peristomal skin around the ileostomy presented with granulation tissue, re-epithelialization and re-pigmentation (**Photo 3**). His wear time increased from a few hours to four days when the pouching system was changed to allow the dermatology team to assess his skin.

The patient was discharged home with the two-piece CeraPlus cut-to-fit convex skin barrier and drainable pouch to manage his ileostomy. He continued with the barrier ring but discontinued the additional hydrocolloid between the two stomas. The patient was changing his own pouching systems and was independent with ostomy care. He was able to get a six day wear time the week of his follow-up appointment because he wanted to wait until his clinic appointment to change his pouching system. The usual wear time for both the ileostomy and urostomy was four days.

Conclusion

Many people with ostomies experience peristomal skin issues and accept them as a normal aspect of having a stoma³. Achieving a good fit around the stoma and preventing leakage as a means of mitigating skin irritation is important. The formulation of a skin barrier also has an impact on the health of the peristomal skin. Finding the right combination of skin barrier formulation, and skin barrier fit is essential to maintaining a healthy peristomal skin environment.
